

for their metastatic disease. Two patients received pembrolizumab as second-line treatment, one after progression on ipilimumab and one after progression on dabrafenib. Four patients were treated with pembrolizumab as third line therapy and one patient received it as a fourth line treatment after progression on vemurafenib, DTIC and ipilimumab. A total of six patients (26%) received ipilimumab during their course of treatment prior to treatment with pembrolizumab. One patient received three intralesional Injections of Interleukin-2 (IL-2) for subcutaneous in transit metastases prior to pembrolizumab therapy.

The objective response rate was evaluated clinically and radiologically with FDG-PET scan as per Percist 1.0 criteria. Our patient population had an objective response rate of 52% (n=12), with a complete response rate of 48%. Our entire cohort received a median of 10 pembrolizumab cycles (range 2-45). Complete response was achieved after a median of 11 cycles of pembrolizumab (range 2-19) (Table 2). One patient presented with partial response after 9 cycles of pembrolizumab, and one patient had stable disease throughout therapy. A total of 10 patients (43%) had disease progression. These patients received a median of 6 pembrolizumab cycles before progression (range 3-25). In the subgroup of patients with a BRAF mutation, 57% received a BRAF +/- MEK inhibitor as first line therapy and 43% received pembrolizumab as first line treatment. When pembrolizumab was given in second line in those BRAF mutated patients, half of those patients presented a CR. Among the BRAF mutated patients who received pembrolizumab as first line, one patient had a CR, one had a partial response and one had progression of disease. At the time of analysis, only one patient was still on pembrolizumab. The most common reasons for treatment discontinuation were complete response and disease progression.

Therapeutic response as per PERCIST 1.0	No. of patients	Median number of cycles of pembrolizumab to achieve response-No. cycles
Complete Response (CR)	11	11
Partial Response (PR)	1	9
Stable Disease (SD)	1	45
Progressive Disease (PD)	10	6

Table 2: Response rate of pembrolizumab in locally advanced and stage IV melanoma.

The median follow-up in this cohort of patients was 27 months (range 6-46 months). Our patients with metastatic melanoma treated with pembrolizumab showed a median OS of 60 months (95% CI: 49.9-182.0). The one, three and 5-yr OS were estimated at 100%, 96% and 77%, respectively (Figure 1). The median PFS was of 29 months (95% CI: 2.8-55.2), with a one and 3-yr PFS estimated at 61% and 45%, respectively (Figure 2). Sixteen patients (70%) were alive at the time of analysis. Progression of disease was the most common cause of death. Amongst those patients, cerebral compression or hemorrhage due to brain metastases represented the most common cause of death. All 11 patients (48%) who achieved a complete response maintained their response and remained disease-free.

Adverse Events

In our cohort of 23 patients, 65% (n=15) of patients experienced adverse events. The most common adverse events were fatigue (22%), pruritus (26%), isolated hypothyroidism (17%), diarrhea (17%), and persistent cough (17%). Two patients reported cutaneous rashes (8%) and one patient presented nausea (4%), all of which were identified as grade 1 or 2 adverse events. Overall, grade 3 and 4 adverse events occurred in 3 patients (13%), all of which were autoimmune related events (Table 3). These adverse events included pancreatitis, colitis, interstitial nephritis, pneumonitis and heart failure. Those immune-mediated adverse events were treated with discontinuation of pembrolizumab, high dose corticosteroids and supportive care. Two patients required hospitalization. All three patients had CR with pembrolizumab. There were no reported treatment-related deaths in our cohort of patients.

Cough	4 (17,4)	4 (17,4)	0	0
Pancreatitis	2 (8,7)	0	1 (4,3)	1 (4,3)
Skin rash	2 (8,7)	2 (8,7)	0	0

Nausea	1 (4,3)	1 (4,3)	0	0
Alopecia	1 (4,3)	1 (4,3)	0	0

*Calculations were based on 23 patients who received at least one dose of Pembrolizumab. Above are listed the adverse events reported between the first dose and 30 days after the last treatment dose. For serious immune related adverse events, a cutoff period of 90 days after the last treatment dose was used. The severity of adverse events was graded according to the CTCAE, version 5.0

Table 3: Pembrolizumab related adverse events.

1* ** 11 1

The Objective Response Rate (ORR) in our cohort of patients was 52% and Complete Response Rate (CRR) was 48% after a median of 11 cycles of pembrolizumab. At the time of data collection, all 11 patients with complete response remained disease free. Our study showed a median OS and PFS of 60 months and 29 months, respectively. When comparing to the oncologic outcomes of the pembrolizumab group in KEYNOTE-006, the results reported in our group study showed a higher response rate with longer OS and PFS. KEYNOTE-006 demonstrated an ORR of 36% and a CRR of 13% [11]. The estimated PFS of our population was 29 months compared to 5.6 months in the KEYNOTE-006 cohort. Multiple factors can explain the overall favorable results reported in this study. First, our cohort of patients was evaluated using FDG-PET scan with the PERCIST criteria, which could overestimate the response rate [15-17]. Using FDG-PET scan and PERCIST criteria instead of computed tomography imaging and RECIST criteria, as used in the KEYNOTE trial, can explain the higher number of complete responders as well as our improved overall response rate. Although our cohort of patients had similar baseline demographic and clinical characteristics as patients enrolled in the KEYNOTE-006 trial, the small cohort size remains a major limitation of this study and limits the direct comparison and generalization of our statistical results.

The favorable safety profile of pembrolizumab observed in this study is consistent with the toxicity that had already been described in the literature [9-11]. Most patients (65%) developed adverse reactions during the treatment period, with a majority of self-limited grade 1 and 2 toxicities. Grade 3 and 4 adverse reactions were reported in 13%. They were all autoimmune related events which were managed medication and discontinuation of treatment with no long-term consequences.

In terms of duration of treatment, patients with complete
