

Detecting Calcified Liver Metastasis in Breast Cancer

Radiology Department of national institute of oncology of Rabat, Morocco

Clinical Image

Calcified liver metastases in breast cancer are rare. We report a case of calcified liver metastases detected on CT scan in a 54-year-old female patient with a history of breast cancer.

On a routine CT scan, calcified liver metastases were detected. In this case, CT scan is a useful tool for the detection of calcified liver metastases (Figure 1), which can be detected on CT scan. Detection of calcified liver metastases is important for the diagnosis of breast cancer (Figure 1).

Treatment of calcified liver metastases in breast cancer is challenging. The mainstay of treatment is systemic therapy, including chemotherapy and targeted therapy. In some cases, local treatment such as radiotherapy or surgical resection may be considered [1,2].

In conclusion, calcified liver metastases in breast cancer are rare. CT scan is a useful tool for the detection of calcified liver metastases. Detection of calcified liver metastases is important for the diagnosis of breast cancer, and a multidisciplinary approach is recommended.
