gynecologic conditions. As a result, diagnosis is frequently delayed, leading to advanced disease stages at presentation. This underscores the critical need for improved awareness among healthcare providers and the general public to recognize the signs and symptoms of fallopian tube cancer promptly [7].

Advancements in diagnostic imaging modalities and tumor marker assays have enhanced our ability to detect fallopian tube cancer, yet definitive diagnosis often requires surgical intervention. The gold standard for diagnosis remains histopathological examination of tissue samples obtained during surgery, highlighting the importance of prompt referral to gynecologic oncologists for suspected cases [8].

Surgical management plays a central role in the treatment of fallopian tube cancer, with the goal of achieving optimal cytoreduction and complete tumor removal. However, due to the anatomical location of the fallopian tubes and their proximity to critical structures such as the ovaries and uterus, surgical resection can be challenging. Multidisciplinary collaboration among gynecologic oncologists, surgeons, medical oncologists, and radiation oncologists is essential to tailor treatment strategies to individual patients and optimize outcomes.

Chemotherapy is commonly employed in the adjuvant or neoadjuvant setting to target residual disease and reduce the risk of recurrence following surgery. However, the optimal chemotherapy regimen for fallopian tube cancer remains a subject of ongoing investigation, with limited data available due to its rarity. Future research efforts should focus on elucidating the molecular pathways
