Citation: Talmoudi A, Azzabi A, Sahtout W, Mrabet S, Guedri Y, et al. (2017) Induction Therapy: Comparison between Poly and Monoclonal Antibodies . J Clin Exp Transplant 2: 118. doi: 10.4172/2475-7640.1000118

the Student's t test for the comparison of two independent sample means. Alpha risk was judged to be statistically signi cant from a 5% threshold.

We included 191 kidney recipients. 64.92% of the patients were received as induction therapy a polyclonal antibody and 35.07% received a monoclonal antibody (basiliximub). A high frequency of male sex was observed in both groups, 61.19% and 66.93% respectively with p=0.427. ere was no signi cant di erence for mean age in both groups, 31.73 ± 13.85 years in G1 *versus* 33.8 ± 12.57 years in G2, p=0.279. e most common initial nephropathy was chronic interstitial nephropathy in both groups, 65.67% and 42.74% respectively with signi cant di erence, p=0.013. e mean number of missmatch was higher in the ATG group (3.33±1.60 *versus* 2.32±1.75) with a signi cant di erence, p=0.001. Most patients in both groups received tacrolimus (50.74% in G1 *versus* 53.22% in G2) with p not signi cant p=0.743.19.40% of G1 patients received ciclosporin *versus* 39.51% in G2, p=0.005 while treatment with MMF alone was more prescribed in G1 (26.86% in G1 *versus* 4.03% in G2) with p=0.001(Table 1).

e occurrence of rejection was higher in the group treated with polyclonal antibodies compared with the basiliximub-treated group but without signi cant di erence (21.77% in G2 *versus* 14.92% in G1), p=0.253. e mean time to onset of acute rejection was shorter in the basiliximub group (11.26 +/-21.98 days *versus* 20.21+/-44.58 days) with no signi cant di erence p=0.37.

Infectious complications were observed particularly in the group treated with polyclonal antibodies with a signi cant di erence for the occurrence of pneumopathies (p=0.005), CMV infection (p=0.045), urinary tract infections (p=0.020).), cystitis (0.038) and digestive tract infections (p=0.035) (Table 2).

e multivariate analysis revealed that the occurrence of pneumonia (p =0.014, IC [0.034-0.681] and urinary tract infections, p=0.04, IC [0.277-0.969] were independently associated with treatment with rATG (Table 3).

No patient in group 1 developed neoplasia, while 10 patients in G2 (8.06%) had a neoplastic complication with a signi cant di erence p=0.017. ere were 3 cases of Kaposi's sarcoma, 2 cases of gra and cavum lymphoma, 1 luberkhunal adenocarcinoma of the colon, 2 common warts, 2 anal condylomas.

We also evaluated the impact of basiliximub induction *versus* polyclonal antibody on gra function.

e delayed gra function was observed more frequently in the group treated with r ATG 15.32% *versus* 11.94% but without signi cant di erence p=0.508.

Gra loss was observed more frequently in the basiliximub group, 8.95% *versus*

Pulmonary and digestive infections are independently associated with rATG treatment. is can be explained by the strong immunosuppression induced by polyclonal antibodies. Wang W and
