

Visualizing Hepatocellular Carcinoma: A Comprehensive Review of Imaging Techniques

Payal Patel*

The most common imaging modalities used in the evaluation of Hepatocellular Carcinoma include ultrasound, computed tomography (CT) and magnetic resonance imaging (MRI). Due to the low uptake of the commonly used radiotracer, 2-[18 F]-2-deoxy-D-glucose (FDG), which results in a high false positive rate, positron emission tomography (PET) has played a minor role in HCC imaging thus far.
