Introduction

Canine allergic dermatitis (CAD) is a common skin condition in dogs, characterized by intense pruritus and erythema. It is caused by an allergic reaction to various environmental allergens, including pollen, dust, and mold. The condition is often diagnosed based on clinical signs and a history of seasonal exacerbations. Treatment typically involves the use of antihistamines and corticosteroids to manage symptoms. However, long-term management often requires allergen avoidance and immunotherapy. This commentary discusses the clinical presentation, diagnosis, and treatment options for CAD in dogs, emphasizing the importance of a thorough history and physical examination in identifying the underlying allergen.
