Introduction

Need is characterized as an overpowering inclination to burn through a substance and its investigation was started in the field of medications, taking into account that, it established a significant base for keeping up with addictions. According to a psychophysiological perspective, it would be a persuasive expression that supports the utilization of both, medications and food.

Mental clarifications based on learning hypotheses, while useful, are insufficient to explain the overwhelming desire for food. That food need appears to impart the neurophysiological premise to the hankering for drugs.

The drugs share some capacity to incite enduring primary changes
